

Aureus ERP — Application Report

Truck It In (Pvt) Ltd — system overview, modules and functionality

1. What the App Is

Aureus ERP is a modular ERP system built on Laravel + Filament, running the day-to-day operations of Truck It In (Pvt) Ltd. It is organized as independent plugins (Accounting, Sales, Purchases, Inventory, Employees/HR, Time Off, Products, Support/Approvals, Plugin Manager) that share a common admin panel, permission system, and multi-company data model. Each plugin owns its own models, migrations and Filament resources, and cross-plugin work always flows through shared services rather than direct table access.

2. Core Modules & What They Do

Accounting — Chart of Accounts, Journal Entries, General Ledger, multi-currency, Trial Balance, Profit & Loss, Balance Sheet, Cash Flow Statement, and Partner Analytics. Supports customer invoices and vendor bills end-to-end, including payment recording, cash transactions and bank transfers.

Banking & Bank Imports — Imports bank statements (CSV/Excel), maps each transaction line to a GL account via Transaction Mapping, matches transfers, and generates draft journals that go through review and posting before hitting the ledger.

FS Tags — A reusable tagging layer that links recurring counterparties/expense types to a GL account, cash-flow category and tax treatment, so future bank-statement rows auto-map instead of needing manual review every time.

Google Drive Inbound Invoices — Watches a Drive folder for incoming vendor invoices/bills, extracts vendor name, amount and document type automatically, and routes anything ambiguous to a human review screen (with per-row "New" tags and a navigation badge) instead of guessing.

Sales — Quotations to Sales Orders, customer invoicing, and the customer-facing order lifecycle.

Purchases — Requests for Quotation to Purchase Orders, vendor bills, and an approval step for orders that need sign-off before becoming a firm purchase.

Inventory & Products — Product catalog, stock operations, and the product/GL account relationships that accounting and sales/purchases depend on.

Employees / HR — Employee records, Employee Requests (claims, document changes, etc.), and an HR hierarchy service that scopes each manager to their own reports.

Time Off — Leave requests and leave allocations, with a multi-step confirm → validate → approve workflow and its own state machine.

Approval Engine — A single, shared approval-request queue used across modules (Drive invoices, time off, bank transaction mapping, purchase orders). Each request tracks who can act on it right now, so the same engine powers both the approve/reject UI and the "how many things need me" badge.

Permissions & Plugin Manager — Role-based access control enforced server-side (not just hidden UI), and a plugin registry that governs which modules are active per installation.

3. Multi-Company & Data Integrity

The system supports multiple companies in one installation. Every accounting query, account picker, and report is expected to scope by company so one company's transactions, accounts, and bank data can never leak into another's. Journal entries preserve balanced debit/credit integrity, posting status, and reconciliation state; posted records are never silently modified.

4. Hardening Work Completed

Beyond day-to-day feature work, a full pass was made across the app to close data-integrity gaps and improve day-to-day usability:

Duplicate-Prevention Audit (Critical + High tier — shipped)

- Database-level unique constraints added for account move numbers, journal codes, tax definitions (company + name + amount + type), employee identity fields (ID/SSN/SIN/passport), and product reference/barcode — closing the root cause behind a duplicate-tax-chip bug found during testing.
- Journal-move confirmation ("post/confirm") now locks the record inside a database transaction before acting, closing a double-submit race where the same move could be confirmed twice.
- Any pre-existing duplicate rows were renamed (never deleted) with a clear "-DUPLICATE-{id}" marker so history stays intact while the new constraint takes effect going forward.

Readability / Professionalism Pass (shipped)

- Added navigation badges (with color) that surface counts of items actually needing attention — Approval Requests, Employee Requests, Time Off, Leave Allocations, Bank Transaction Mapping, Sales Quotations and Purchase Quotations — each scoped to what the logged-in user can actually act on, not a raw company-wide count.
- Reordered default table sorting on those same screens so unresolved/oldest-pending items surface first instead of being buried by ID order.
- Gave the Time Off status enum proper badge colors, replacing plain uncolored badges.

Live-Verified Fixes From End-to-End Testing

- Balance Sheet no longer flips Total Equity positive during a net loss (a sign-handling bug).
- Customer/vendor payment recording now has a server-side re-check preventing the same invoice from being paid twice.
- Payment cancellation now properly unreconciles before removing a record, instead of corrupting reconciliation state.
- Journal Entry account picker is now company-scoped (previously showed every company's accounts).
- GST/sales-tax registration flag corrected so tax-compliance behavior matches the company's real status.
- FS Tags that were missing a linked GL account were given dedicated expense accounts (Fuel, Vehicle Maintenance, Toll Charges, Driver Payroll), so bank-statement auto-mapping works for those categories.
- Google Drive invoice extraction fixed for vendor-name misdetection, a stray-byte amount-parsing bug, and an ambiguous-document-type guess that used to default incorrectly to "customer invoice."

This report reflects the state of the application as of the work completed in this engagement. For exact code-level detail, the Git history on the project's repository is the source of truth.
